

MRCSP - Large-Scale CO₂-Enhanced Oil Recovery and Geologic Storage Test in Midwestern USA

Carbon Sequestration Leadership Forum
PIRT Group Meeting
Washington, DC
November 4, 2013

Presented by:
Neeraj Gupta, Ph.D.
Senior Research Leader,
Battelle, Columbus, Ohio
gupta@battelle.org

DOE/NETL Cooperative Agreement # DE-FC26-0NT42589

MRCSP – cornerstone of the Battelle’s program on the CCUS technology development

- AEP Mountaineer Projects**
- Site Characterization, Design
 - Permitting, Construction
 - Operations, workover
 - Post-Injection Monitoring
 - >150,000 hours of safe drilling

- FutureGen Program**
- 1 MT/yr scale
 - Design/costing
 - Class VI permitting

Wellbore Integrity

Simplified Modeling

Storage Feasibility in Sichuan Basin China

Ohio Valley Characterization, Basin-Scale Modeling

Private Client Studies – Domestic and Global

Emerging Program in Brine Disposal, EOR, Shale Gas

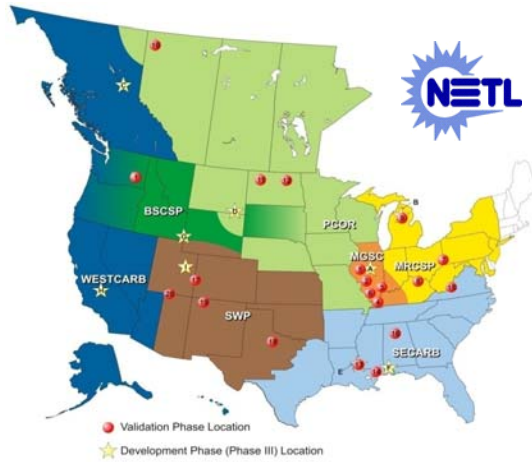

Regional Carbon Partnership

- Regional Mapping
- Policy & Regulation
- Small-Scale Tests
- Large-Scale Test
- EOR and Storage
- Exploration

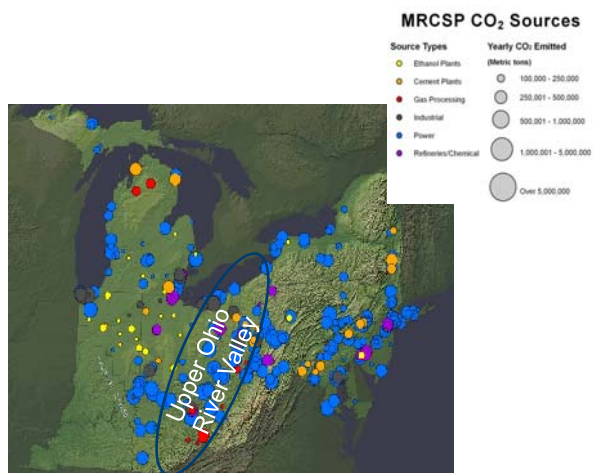

The MRCSP assesses viability of carbon sequestration

- Established in 2003 by Battelle with DOE-NETL funds – Currently in Phase III
- Led by Battelle, there are 40 organizations from non-profit, government, and commercial entities
- Mission – The premier resource for CO₂ storage and utilization expertise in the region

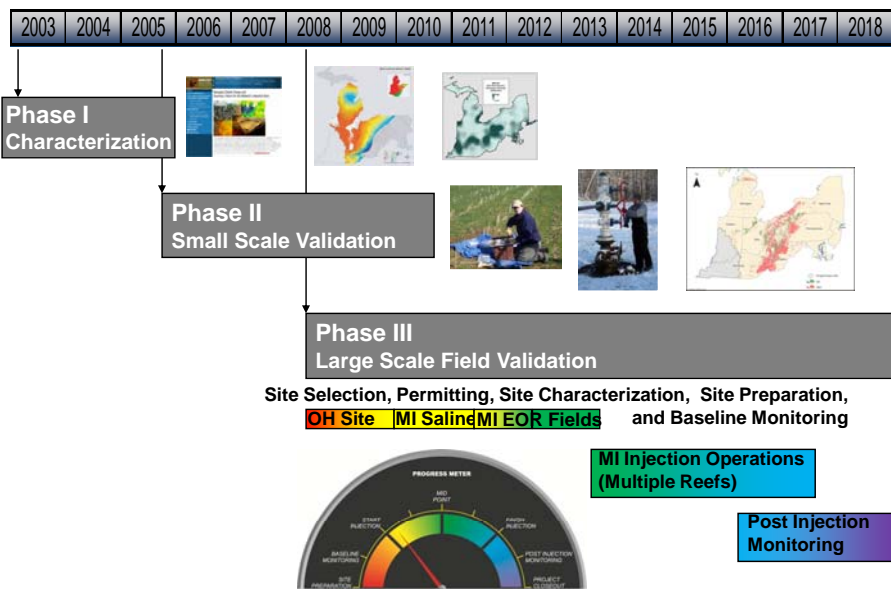

MRCSP region: Many CO₂ emission sources with dependence on coal

- CO₂ storage/utilization technologies key to affordable energy supplies
- Environmental/climate issues and shale gas, are leading to energy supply transition
- Coal continues to be dominant fuel source, but will be impacted due to emission limits

Overall schedule for MRCSP – 10 Years of achievements and more to come!

5

CO₂ Storage resources – significant but heterogeneous potential

- Many promising units for CO₂ storage including saline formations, depleted oil/gas fields, and potentially organic shales, and coal beds
- Mapping and understanding the storage zones is an ongoing effort
- Primary targets include Mt. Simon Sandstone along the arches and carbonate layers in deeper basins

Depleted Oil and Gas Fields:
~8.500 GT

Deep Saline Formations:
~49-194 GT
(not including offshore)

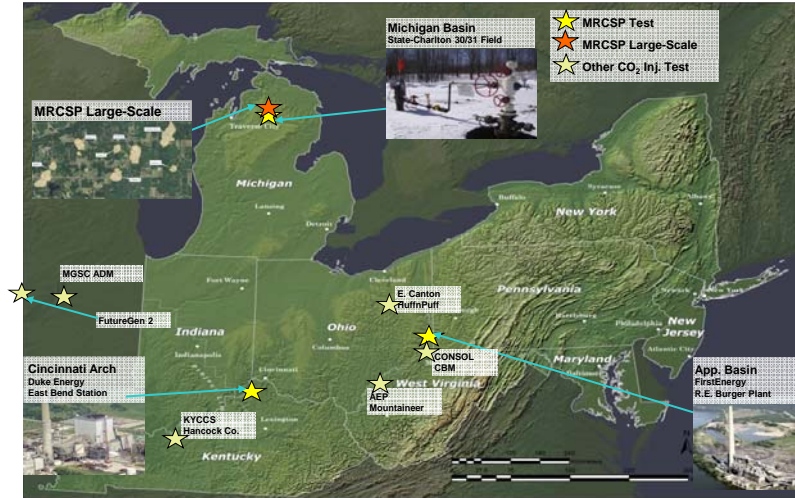

Organic Shales: ~2-30 GT
Unmineable Coal: ~1 GT

6

Many field tests demonstrate heterogeneous storage potential in MRCSP region

Region is home to several field tests – but many more are needed

MRCSP Ten-Years - Key Observations

Technical Issues

- Small-scale tests extremely useful in proving safety and effectiveness – *we need more of these*
- Injectivity different at each site
- Monitoring data redefined geologic model in all cases
- Regional heterogeneity necessitates extended mapping and multiple field tests
- Continued testing and evaluation of monitoring technologies needed to build confidence

Social Issues

- Proactive outreach and collaboration with host site teams crucial for public acceptance

Permitting

- Class V experimental permits enabled testing
- EOR sites can enable CCUS deployment and research – but only have one site in MRCSP region

Other

- RCSP research can also benefit other energy R&D – brine disposal, wellbore integrity, shale gas

MRCSP study fields are in multiple oil production stages

Oil fields are in various production life-cycle stages

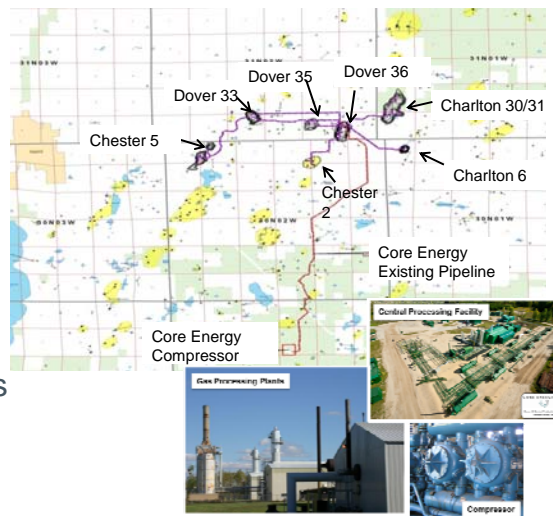

- **Late-Stage EOR Reefs**
Undergone extensive primary and CO₂-EOR – highly depleted
- **Active EOR Reefs**
Completed primary oil recovery and CO₂-EOR is under way
- **Pre-EOR Reefs** – New CO₂ EOR
Undergone primary oil recovery but no CO₂-EOR yet

Existing EOR infrastructure enables cost effective research for MRCSP tests

• Infrastructure:

- CO₂ uptake from capture
 - Compression and dehydration systems
 - Pipelines for transport
 - Central processing facility (Dover 36)
 - Injection and production-monitoring wells (7 fields)
 - Monitoring and measurement systems
- Total system capacity is >1200 tonnes/day (10-15% of 500MW coal-based plant)

Dover 36 Processing Facility – central hub for fluids and data flow

MRCSP Project Schedule

▲ Approval of workplan required before proceeding with field work.
● Approval of basline geologic report required before injection can begin.

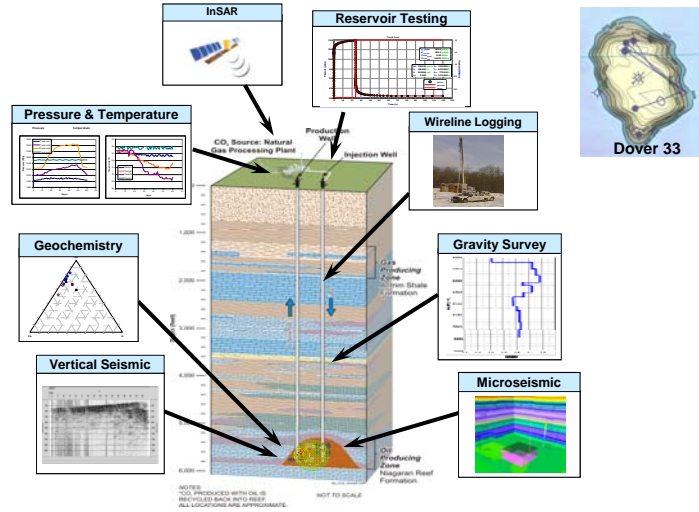

MRCSP field test research objectives

- 
Site Characterization Assess the variability among adjacent reefs
- 
Reservoir Models Validate using injection and production
- 
Operational Models Predict CO₂ storage and oil production; suggest approaches to optimize both
- 
Monitoring Techniques and Equipment Identify cost effective and useful techniques and methods
- 
Reef Capacity and Injectivity Identify key parameters and variability; address uncertainty

Geologic Setting – Complex Reef Structures

Highly depleted field provides a test bed for advanced monitoring technologies

Monitoring options under testing at Dover 33 field

MRCSP Dover 33 field monitoring program

| Activity | Before Injection | Early Injection | Mid Injection | Late Injection | After Injection |
|---------------------------|------------------|-----------------|---------------|----------------|-----------------|
| CO ₂ Injection | | X | X | X | |
| Pressure and temperature | X | X | X | X | X |
| Wireline Logging | X | | X | | X |
| Fluid Sampling | X | | X | | X |
| Borehole Gravity | X | | | | X |
| VSP | X | | | | X |
| Microseismic | X | | | Maybe | |
| InSAR | X | X | X | X | X |

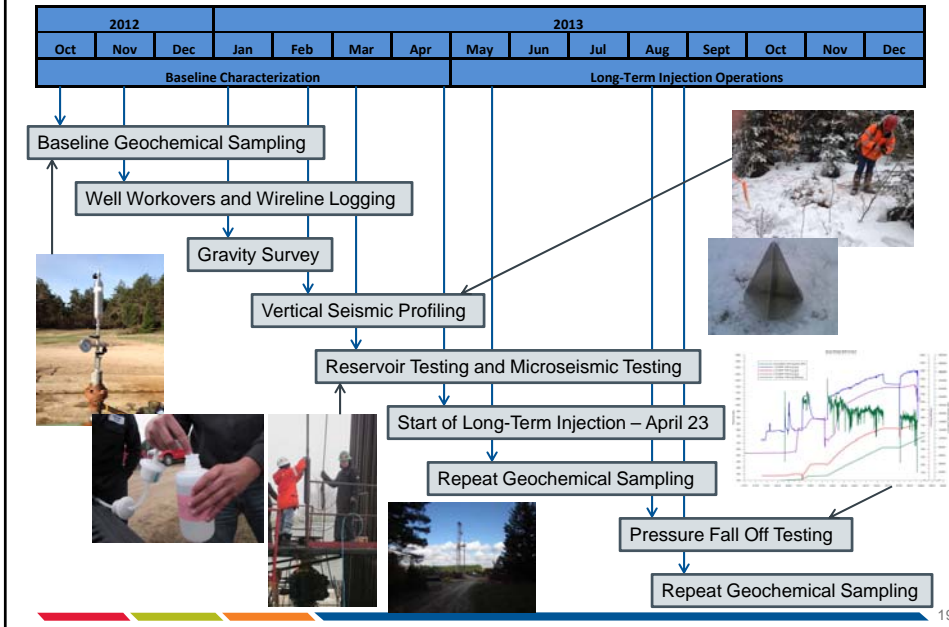

Borehole gravity meter being assembled

- Late stage, Dover 33, serves as main test bed for monitoring techniques
- Instrumented wells and pipelines in active fields to track CO₂ injection and CO₂, brine, and oil production
- Lessons learned will be applied to design MVA plan for newly targeted field for EOR (to be determined)

Model assessing feasibility of the borehole gravity meter to measure changes in formation density in response to CO₂

MRCSP Phase III Field Activities – Dover 33

Safety Considerations for MRCSP Fieldwork

- Wide variety of work -- wide range of safety considerations
- All work completed safely to date!

Fluid Sampling and Reservoir Testing – high pressure fluids, well work

InSar ACRs – heavy equipment operation

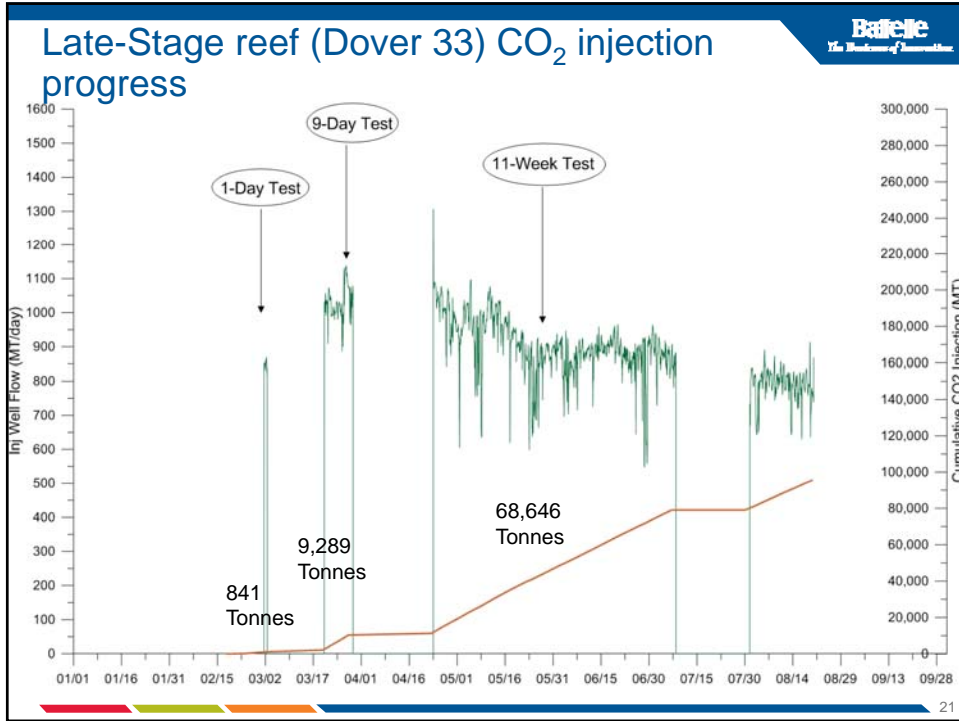

Well Workovers – well control, overhead hazards, heavy equipment

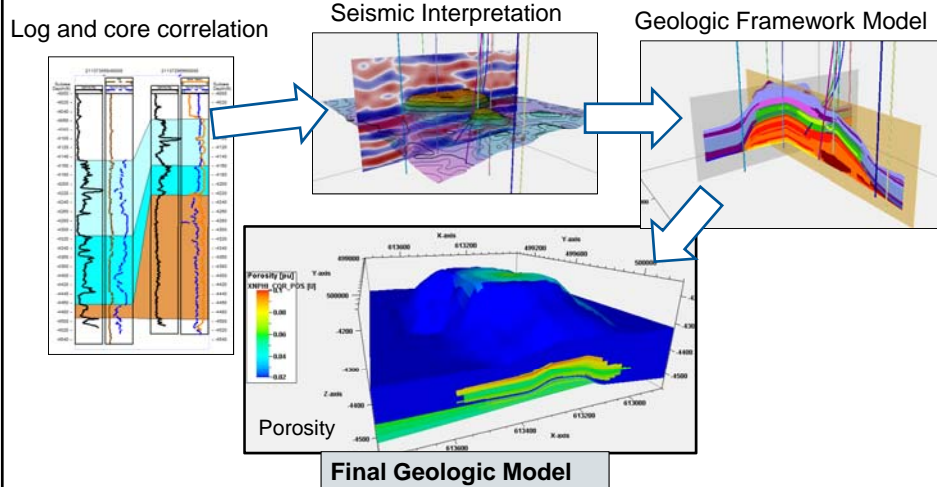

Seismic Activities – well work, explosive hazards

Wireline Logging – well work, radiologic hazards

Developing detailed geologic model work for MRCSP based on seismic and well log data

The modeling integrates seismic and well log data
Provides basis for fluids flow models

MRCSP Dynamic reservoir simulations

Expected Outcome:

- Full accounting for (1) reservoir geology and (2) compositional phase behavior

Strategy:

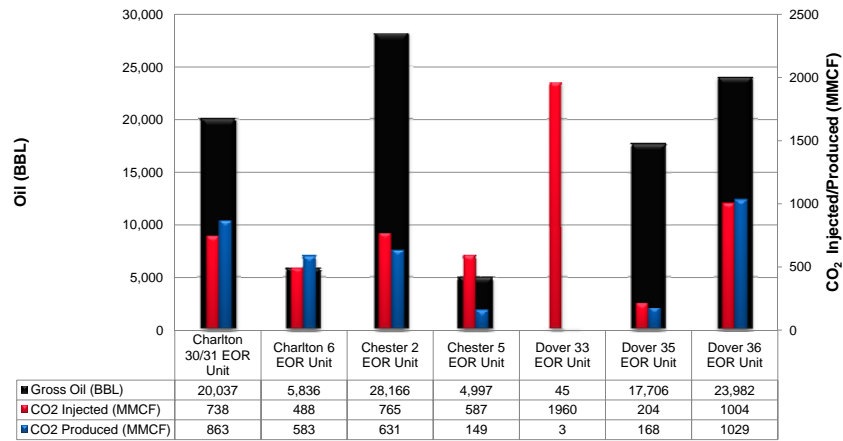

- **CO₂-Prophet** for initial simulations
- **GEM** (Computer Modeling Group) to model multiphase flows for CO₂-EOR
- Requires detailed information about (1) rock / fluid properties and (2) production history
- Can be used for all phases of history matching (primary, CO₂-EOR, depleted), flood design and production forecasting
- Possible partial or full coupling of flow, geochemistry, and geomechanics

MRCSP – Understanding CO₂-EOR System-wide operations

- Data collection and reporting from all fields
- Compilation and review of historic operations data
- Systematic calibration of flow meters

2013 YTD (end August) Production by Reefs

MRCSP Facility-wide CO₂ supply and injection/production history

- Chester 10 and recycled CO₂ Supply since 2006 and during 2013
- Data useful for history matching in models and evaluating CO₂ retention

2013 - CO₂ from Chester 10, Produced and Total at Dover 36

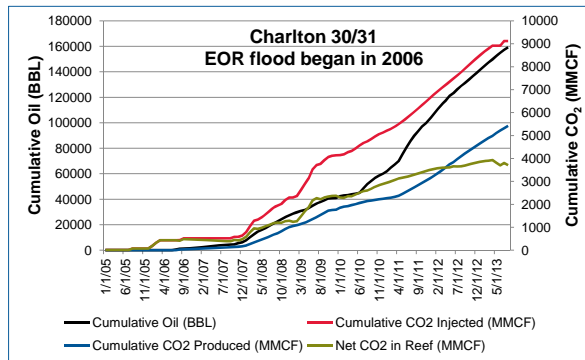

Monthly CO₂ Availability - Chester 10 Pure CO₂, Produced CO₂ and Total CO₂

Monitoring in Active EOR Reefs

- Work plan approved by DOE
 - Review historical operations
 - Selected piggyback monitoring
 - Model one reef in detail
 - Evaluate mass balance and retention

MRCSP Outreach Goals

- ❑ Support the large volume injection test
 - ❑ Updated communication plan for restructured project
- ❑ Maintain reputation of MRCSP as a neutral and credible source of scientific information on CCS
 - ❑ Over 20 Topical Reports available
 - ❑ Over 30 Presentations and Briefings available on MRCSP Website
- ❑ Improve public understanding and acceptance of CCS
 - ❑ Synthesizing project results into key findings and messages for stakeholders.
- ❑ Increase public understanding of EOR, subsurface activities, and their role in the larger energy mix
 - ❑ Speaking at conferences and meeting with trade associations

Site Specific Outreach Activities

- Maintaining regulatory and community relationships
 - ~250 VSP shot points and 29 artificial reflectors installed on private property
- Monitoring events and issues that could have a bearing on public views of the project (e.g., shale plays, “fracking”).
- Building upon a broad suite of communications materials and tools to support project
 - Developing new outreach materials
 - Posting “Project Snapshots” on the MRCSP website
- Hosting site tours

Utilization of Carbon Dioxide for Enhanced Oil Recovery

What is Enhanced Oil Recovery?

Oil fields are found in layers of sedimentary rock buried thousands to thousands of feet below the surface. The crude oil is porous and permeable rock layers separated from organic material, such as plankton and algae, and was deposited and preserved millions of years ago. Crude oil is typically a fluid mixture that, like carbon dioxide, is less dense than water and sedimentary heat and tends to migrate towards the surface. Conventional oil fields are formed when the migrating oil is trapped by impermeable rock layers. Many oil fields have trapped heavier oil and gas fluids in the subsurface for millions of years. Today, sophisticated techniques have been developed for finding and producing oil fields.

When an oil field is first produced, the natural high pressure in the formation, which is a function of burial depth below the surface, helps to push the oil out of the formation and to the surface. In the early days of oil industry, this sometimes led to the famous “gushers” seen in history books. Typically, active oil fields have pressure in great enough to produce roughly 10-20% of the oil in an oil field. Once the pressure is depleted during the natural or “primary” production phase, various techniques are employed to restore a pressure drive in the oil field and reduce the distance or viscosity of the oil so that additional oil can be recovered. In addition to water flooding, there are 7 major approaches used in enhanced oil recovery (EOR):

- **surfactant:** Surfactant is injected to thin the oil and help it flow;
- **chemical:** polymers or surfactants that behave like soap are injected to break up the oil and help release it from the rock surfaces in the pore space, well;
- **gas:** natural gas or hydrocarbon, nitrogen or carbon dioxide is injected to increase reservoir pressure and to help thin the oil so it can flow to the surface.

Figure 1 illustrates how gas – in this case compressed carbon dioxide which has liquid-like density but gas-like flow properties – is used for EOR. Carbon dioxide and other gases are injected into the oil reservoir through an injection well. The carbon dioxide mixes (becomes miscible) with the oil, swelling and decreasing the viscosity of the oil. At the same time, the injected carbon dioxide and some ex-situ brine pressure in the oil field, helping to push the oil towards the production well. The resulting oil, carbon dioxide, and water mix is brought to the surface as a closed loop system that allows the operator to separate the carbon dioxide and water for reuse while the oil, and in some cases, the related products, are sold onto the market. In this process, carbon dioxide displaces oil and some of it remains behind permanently. Because not a lot of surplus carbon dioxide is available as a form that can be used for EOR, operators work diligently to secure as much of the carbon dioxide as they can. Despite these efforts, approximately 20-30% of the injected carbon dioxide remains in the ground.

November 2012

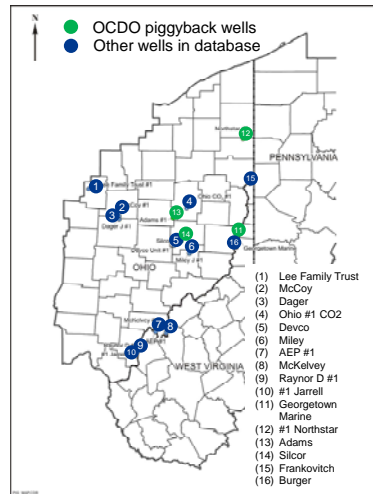

MRCSP Fact Sheet on
Enhanced Oil Recovery (EOR)

Knowledge sharing continues to be an important outcome of the MRCSP program

- FutureGen2.0 geologic storage program
- Appalachian Basin and Ohio
 - AEP Mountaineer site
 - CO₂-utilization for EOR and storage options
 - Wellbore integrity assessment
 - Brine disposal options
- International - World Bank CCUS capacity building in China
 - Hosting delegation visits
 - Sichuan basin storage potential
- Dialogue with other partnerships

Finding storage options in Appalachian Basin

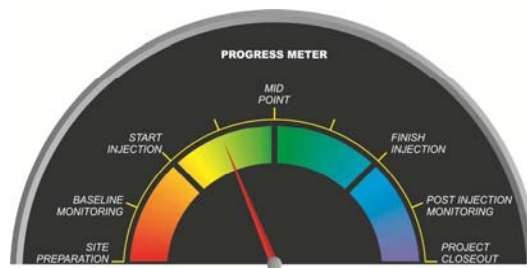

- Battelle is working with oil/gas operators to obtain crucial geologic data for mapping storage zones
- Funded by Ohio Coal Development Office as a joint effort with MRCSP

Copper Ridge
vuggy Dolomite
Core 8370'

MRCSP status and plans

- MRCSP Phase III injection began Feb. 2013 –
- ~350K tonnes till Oct. 2013 in Dover 33 and other active reefs
- Up to 500,000 tonnes of CO₂ injection planned in Dover 33 depleted reef
- Additional fields for new CO₂-EOR tests with ~500,000 tonnes planned
- >200,000 tonnes injection monitored in active reefs by Oct. 2013
- A period of monitoring after completion of injection
- Wells to be returned for normal operations by Core Energy at the end
